Brain Tumors: an Introduction

Overview
A brain tumor is an abnormal growth of cells inside the brain or skull; some are benign, others malignant. Tumors can grow from the brain tissue itself (primary), or cancer from elsewhere in the body can spread to the brain (metastasis). Treatment options vary depending on the tumor type, size and location. Treatment goals may be curative or focus on relieving symptoms. Many of the 120 types of brain tumors can be successfully treated. New therapies are improving the life span and quality of life for many people.

What is a brain tumor?
Normal cells grow in a controlled manner as new cells replace old or damaged ones. For reasons not fully understood, tumor cells reproduce uncontrollably.

A primary brain tumor is an abnormal growth that starts in the brain and usually does not spread to other parts of the body. Primary brain tumors may be benign or malignant.

A benign brain tumor grows slowly, has distinct boundaries, and rarely spreads. Although its cells are not malignant, benign tumors can be life threatening if located in a vital area.

A malignant brain tumor grows quickly, has irregular boundaries, and spreads to nearby brain areas. Although they are often called brain cancer, malignant brain tumors do not fit the definition of cancer because they do not spread to organs outside the brain and spine.

Metastatic (secondary) brain tumors begin as cancer elsewhere in the body and spread to the brain. They form when cancer cells are carried in the blood stream. The most common cancers that spread to the brain are lung and breast.

Whether a brain tumor is benign, malignant, or metastatic, all are potentially life-threatening. Enclosed within the bony skull, the brain cannot expand to make room for a growing mass. As a result, the tumor compresses and displaces normal brain tissue. Some brain tumors cause a blockage of cerebrospinal fluid (CSF) that flows around and through the brain. This blockage increases intracranial pressure and can enlarge the ventricles (hydrocephalus). Some brain tumors cause swelling (edema). Size, pressure, and swelling all create "mass effect," which cause many of the symptoms (Fig. 1).

Types of brain tumors
There are over 120 different types of brain tumors. Common brain tumors include:

Gliomas
- Astrocytoma
  - Pilocytic Astrocytoma (grade I)
  - Diffuse Astrocytoma (grade II)
  - Anaplastic Astrocytoma (grade III)
  - Glioblastoma Multiforme (grade IV)
- Oligodendrogioma (grade II)
  - Anaplastic Oligodendrogioma (grade III)
- Ependymoma (grade II)
  - Anaplastic Ependymoma (grade III)

Craniopharyngioma
Epidermoid
Lymphoma
Meningioma
Schwannoma (neuroma)
Pituitary adenoma
Pinealoma (pineocytoma, pineoblastoma)
Medulloblastoma
The World Health Organization (WHO) developed a classification and grading system to standardize communication, treatment planning, and predict outcomes for brain tumors. Tumors are classified by their cell type and grade by viewing the cells, usually taken during a biopsy, under a microscope.

- **Cell type.** Refers to the cell of origin of the tumor. For example, nerve cells (neurons) and support cells (glial and schwann cells) give rise to tumors. About half of all primary brain tumors grow from glial cells (gliomas). There are many types of gliomas because there are different kinds of glial cells.

- **Grade.** Refers to the way tumor cells look under the microscope and is an indication of aggressiveness (e.g., low grade means least aggressive and high grade means most aggressive) (Table 1). Tumors often have a mix of cell grades and can change as they grow. Differentiated and anaplastic are terms used to describe how similar or abnormal the tumor cells appear compared to normal cells.

**Table 1. Glioma Grading Scale.**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Slow growing cells&lt;br&gt;Cells appear almost normal&lt;br&gt;Least malignant&lt;br&gt;Usually associated with long-term survival</td>
</tr>
<tr>
<td>II</td>
<td>Relatively slow growing cells&lt;br&gt;Abnormal cell appearance&lt;br&gt;Can invade nearby tissue&lt;br&gt;Sometimes recur as a higher grade tumor</td>
</tr>
<tr>
<td>III</td>
<td>Actively reproducing abnormal cells&lt;br&gt;Abnormal cell appearance&lt;br&gt;Infiltrate normal tissue&lt;br&gt;Tend to recur, often as a higher grade</td>
</tr>
<tr>
<td>IV</td>
<td>Rapidly reproducing abnormal cells&lt;br&gt;Very abnormal cell appearance&lt;br&gt;Area of dead cells (necrosis) in center&lt;br&gt;Form new blood vessels to maintain growth</td>
</tr>
</tbody>
</table>

**What causes brain tumors?**

Medical science neither knows what causes brain tumors nor how to prevent primary tumors that start in the brain. People most at risk for brain tumors include those who have:

- cancer elsewhere in the body
- prolonged exposure to pesticides, industrial solvents, and other chemicals
- inherited diseases, such as neurofibromatosis

**What are the symptoms?**

Tumors can affect the brain by destroying normal tissue, compressing normal tissue, or increasing intracranial pressure. Symptoms vary depending on the tumor’s type, size, and location in the brain (Fig. 2). General symptoms include:

- headaches that tend to worsen in the morning
- seizures
- stumbling, dizziness, difficulty walking

**Frontal lobe** tumors may cause:
- Behavioral and emotional changes
- Impaired judgment, motivation and inhibition
- Impaired sense of smell or vision loss Paralysis on one side of the body
- Reduced mental abilities and memory loss

**Parietal lobe** tumors may cause:
- Impaired speech
- Problems writing, drawing, naming
- Spatial disorders and eye-hand coordination

**Occipital lobe** tumors may cause:
- Vision loss in one or both eyes, visual field cuts
- Blurred vision, illusions, hallucinations

**Temporal lobe** tumors may cause:
- Difficulty speaking and understanding language
- Short-term and long-term memory problems
- Increased aggressive behavior

**Brainstem** tumors may cause:
- Behavioral and emotional changes
- Difficulty speaking and swallowing
- Drowsiness
- Hearing loss
- Muscle weakness on one side of the face (e.g., head tilt, crooked smile)
- Muscle weakness on one side of the body
- Uncoordinated gait
- Drooping eyelid or double vision
- Vomiting

**Pituitary gland** tumors may cause:
- Increased secretion of hormones (Cushing’s Disease, acromegaly)
- A stop in menstruation
- Abnormal secretion of milk
- Decreased libido
• speech problems (e.g., difficulty finding the right word)
• vision problems, abnormal eye movements
• weakness on one side of the body
• increased intracranial pressure, which causes drowsiness, headaches, nausea and vomiting, sluggish responses

Who is affected?
The American Brain Tumor Association estimates that about 80,000 people will be diagnosed with a primary brain tumor in the US this year. Metastatic (secondary) brain tumors are five times more common than primary brain tumors and they occur in 10% to 30% of cancer patients. People are surviving cancer longer than ever before. As a result, metastatic brain tumors will likely increase in the years to come. Although brain tumors can occur at any age, they are most common in children 3 to 12 years old and in adults 40 to 70 years old.

How is a diagnosis made?
First, the doctor will obtain your personal and family medical history and perform a complete physical examination. In addition to checking your general health, the doctor performs a neurological exam to check mental status and memory, cranial nerve function (sight, hearing, smell, tongue and facial movement), muscle strength, coordination, reflexes, and response to pain. Additional tests may include:

• Audiometry, a hearing test performed by an audiologist, detects hearing loss due to tumors near the cochlear nerve (e.g., acoustic neuroma).
• An endocrine evaluation measures hormone levels in your blood or urine to detect abnormal levels caused by pituitary tumors (e.g., Cushing’s Disease).
• A visual field acuity test is performed by a neuro-ophthalmologist to detect vision loss and missing areas in your field of view.
• A lumbar puncture (spinal tap) may be performed to examine cerebrospinal fluid for tumor cells, proteins, infection, and blood.

Imaging tests
• **Computed Tomography** (CT) scan uses an X-ray beam and a computer to view anatomical structures. It views the brain in slices, layer-by-layer, taking a picture of each slice. A dye (contrast agent) may be injected into your bloodstream. CT is very useful for viewing changes in bony structures.
• **Magnetic Resonance Imaging** (MRI) scan uses a magnetic field and radiofrequency waves to give a detailed view of the soft tissues of the brain. It views the brain 3-dimensionally in slices that can be taken from the side or from the top as a cross-section. A dye (contrast agent) may be injected into your bloodstream. MRI is very useful to evaluate brain lesions and their effects on surrounding brain (Fig. 3).

Biopsy
If a diagnosis cannot be made clearly from the scans, a biopsy may be performed to determine what type of tumor is present. Biopsy is a procedure to remove a small amount of tumor cells to be examined by a pathologist under a microscope. A biopsy can be taken as part of an open surgical procedure to remove the tumor or as a separate diagnostic procedure, known as a needle biopsy. A small burr hole is drilled in the skull so that a hollow needle can be guided into the tumor and a tissue sample removed (Fig. 4). A stereotactic frame and a computer are often used to help precisely locate the tumor and direct the needle to deep tumors in critical locations.

Biomarkers or genetic mutations found in the tumor may help determine prognosis. These include: **IDH1, IDH2, MGMT**, and 1p/19q co-deletion.

Who treats brain tumors?
Because there are so many kinds of brain tumors and some are complex to treat, many doctors may be involved in your care. Your team may include a neurosurgeon, oncologist, radiation oncologist, radiologist, neurologist, and neuro-ophthalmologist.

What treatments are available?
Treatment options vary depending on the tumor type, grade, size and location; whether it has spread; and your age and general health. The goal of treatment may be curative or focus on relieving symptoms (palliative care). Treatments are often used in combination with one another. The goal is
to remove all or as much of the tumor as possible through surgery to minimize the chance of recurrence. Radiation therapy and chemotherapy are used to treat tumors that cannot be removed by surgery alone. For example, surgery may remove the bulk of the tumor and a small amount of residual tumor near a critical structure can later be treated with radiation.

Observation
Sometimes the best treatment is observation. For example, benign, slow growing tumors that are small and have few symptoms may be observed with routine MRI scans every year until their growth or symptoms necessitate surgery. Observation may be the best option for people who are older or with other health conditions.

Medication
Medications are used to control some of the common side effects of brain tumors.

- Steroids, such as dexamethasone (Decadron), are used to reduce swelling and fluid build-up (edema) around the tumor. Because steroids can cause stomach ulcers and gastric reflux, famotidine (Pepcid) or pantoprazole (Protonix) are prescribed to reduce the amount of acid produced in the stomach.
- Furosemide (Lasix) or mannitol (Osmitrol) may be used to control edema and swelling.
- Anticonvulsants are used to prevent or control seizures. The most common ones include phenytoin (Dilantin), valproic acid (Depakote), carbamazepine (Tegretol), and levetiracetam (Keppra).

Surgery
Surgery is the treatment of choice for brain tumors that can be reached without causing major injury to vital parts of the brain. Surgery can help to refine the diagnosis, remove as much of the tumor as possible, and release pressure within the skull. A neurosurgeon performs a craniotomy to open the skull and remove the tumor (Fig. 5). Sometimes only part of the tumor is removed if it is near critical areas of the brain. A partial removal can still relieve symptoms. Radiation or chemotherapy may be used on the remaining tumor cells.

Image-guided surgery, tumor fluorescence, intraoperative MRI/CT, and functional brain mapping have improved the surgeon’s ability to precisely locate the tumor, avoid injury to vital brain areas, and confirm the amount of tumor removal while in the operating room.

Laser Interstitial Thermal Therapy
Laser ablation is a minimally invasive treatment that transmits heat to “cook” brain tumors from the inside out. A probe is inserted to the tumor through a burr hole in the skull. The laser catheter is guided with real-time MRI.

Figure 4. During a needle biopsy, a hollow cannula is inserted into the tumor. Small biting instruments remove bits of tumor for the pathologist to examine and determine the exact tumor cell type.

Figure 5. Surgery involves cutting a window in the skull (craniotomy) to remove the tumor.
Radiation
Radiation therapy uses controlled, high-energy rays to treat brain tumors. Radiation damages the DNA inside cells, making them unable to divide and grow. The benefits of radiation are not immediate but occur with time. Aggressive tumors, whose cells divide rapidly, tend to respond quickly to radiation. Over time, the abnormal cells die and the tumor may shrink. Benign tumors, whose cells divide slowly, may take months to show an effect.

Pinpoint accuracy is critical so that the lethal dose is applied only to the tumor and not to surrounding healthy tissues. There are two ways to deliver radiation, external and internal beams.

External-beam radiation is delivered from outside the body by a machine that aims high-energy rays at the tumor (Fig. 6).

- **Stereotactic radiosurgery (SRS)** delivers a high dose of radiation during one or five sessions. A frame or mask is used to keep the patient immobile.
- **Fractionated radiotherapy** delivers lower doses of radiation over many visits. Patients return daily over a period of 5 to 6 weeks to receive the complete radiation dose.
- **Proton beam therapy** delivers accelerated proton energy to the tumor at a specific depth. The radiation beam does not go beyond the tumor.
- **Whole brain radiotherapy (WBRT)** delivers the radiation dose to the entire brain. It may be used to treat multiple brain tumors and metastases.

Internal radiation (brachytherapy) is delivered from inside the body. After the patient undergoes a craniotomy to remove the tumor, the radioactive seeds, or implants, are placed inside the empty tumor cavity. The radiation dose is delivered to the first few millimeters of tissue in the cavity, where malignant cells may still remain. Patients have no risk of radiation injury to other parts of their own body or to others around them because the dose is short-lived.

Chemotherapy
Chemotherapy drugs work by disrupting cell division. Over time, chemotherapy causes the abnormal cells to die and the tumor may shrink. This treatment can also damage normal cells, but they can repair themselves better than abnormal cells. Treatment is delivered in cycles with rest periods in between to allow the body to rebuild healthy cells. Chemotherapy drugs can be taken orally as a pill, intravenously (IV), or as a wafer placed surgically into the tumor. The drugs most commonly used to treat brain tumors are temozolomide (Temodar) and bevacizumab (Avastin). The most common side effects are...
nausea, low blood counts, infections, fatigue, constipation, and headaches. Chemotherapy is also used to increase tumor cell death during radiation therapy.

Some chemotherapy drugs (BCNU wafer) are applied locally to the tumor bed after the tumor has been removed. By applying it directly to the diseased area of the brain, side effects are limited and the drug has a more beneficial effect.

Chemotherapy is typically used for high-grade gliomas; it is not routinely used for benign tumors.

Adjunct therapies
- Immunotherapy, or biotherap y, activates the immune system (T cells and antibodies) to destroy tumor cells. Research is exploring ways to prevent or treat cancer through vaccines.
- Gene therapy uses viruses or other vectors to introduce new genetic material into tumor cells. This experimental therapy can cause tumor cells to die or increase their susceptibility to other cancer therapies.
- Hyperbaric oxygen uses oxygen at higher than normal levels to promote wound healing and help fight infection. It may also improve the tumor’s responsiveness to radiation. Currently it is being used to help the body naturally remove dead tumor cells and treat radiation necrosis.

Tumor Treating Fields or TTFields
Tumor treating field therapy slows and reverses tumor growth by preventing cells from dividing. TTF is used for the treatment of glioblastoma (GBM) in combination with temozolomide in adults who have been newly diagnosed. It is also approved for treatment of recurrent GBM after surgical and radiation options have been exhausted. Treatment involves wearing a device resembling a bathing cap that delivers electromagnetic energy to the scalp. Patients wear the device all the time.

Clinical trials
Clinical trials are research studies in which new treatments—drugs, diagnostics, procedures, and other therapies—are tested in people to see if they are safe and effective. Research is always being conducted to improve the standard of medical care. Information about current clinical trials, including eligibility, protocol, and locations, are found on the Web. Studies can be sponsored by the National Institutes of Health (see clinicaltrials.gov) as well as private industry and pharmaceutical companies (see www.centerwatch.com).

Recovery & prevention
Self care
Your primary care doctor and oncologist should discuss any home care needs with you and your family. Supportive measures vary according to your symptoms. For example, canes or walkers can help those having trouble walking. A plan of care to address changes in mental status should be adapted to each patient’s needs.

Driving privileges may be suspended while you are taking anti-seizure medication. As each state has different rules about driving and seizures, discuss this issue with your doctor.

It may also be appropriate to discuss advance medical directives (e.g., living will, health care proxy, durable power of attorney) with your family to ensure your medical care and wishes are followed.

Rehabilitation
Because brain tumors develop in parts of the brain that control movement, speech, vision and thinking, rehabilitation may be a necessary part of recovery. Although the brain can sometimes heal itself after the trauma of treatment, it will take time and patience. A neuropsychologist can help patients evaluate changes caused by their brain tumor and develop a plan for rehabilitation. A neuropsychological evaluation assesses the patient’s emotional state, daily behavior, cognitive (mental) abilities, and personality. Physical therapy, occupational therapy, and speech therapy may be helpful to improve or correct lost functions.

Recurrence
How well a tumor will respond to treatment, remain in remission, or recur after treatment depends on the specific tumor type and location. A recurrent tumor may be a tumor that still persists after treatment, one that grows back some time after treatment destroyed it, or a new tumor that grows in the same place as the original one.

When a brain tumor is in remission, the tumor cells have stopped growing or multiplying. Periods of remission vary. In general, benign tumors recur less often than malignant ones.

Since it is impossible to predict whether or when a particular tumor may recur, lifelong monitoring with MRI or CT scans is essential for people treated for a brain tumor, even a benign lesion. Follow-up scans may be performed every 3 to 6 months or annually, depending on the type of tumor you had.
